

# Interface configuration

## Labeling conventions

- [Application title](#)
- [Custom stylesheets](#)

This documentation explains how to override the default settings so that you can customize Avalon for your own needs.

## Application title

To set the default look for the `:title` yield block in the file `app/views/layout/hydrant.html.erb`

Avalon Media System

To add additional context add a `content_for` block in the current template. The free text will be prepended to the application's default label. For example one screen (`views/media_objects/_basic_metadata.erb`) may be tailored to read

Ingest workflow – Avalon Media System

### Yield block for titles

```
<p><%= content_for :title do %>Search results for params[:q].sanitize<% end %></p>
```

## Custom stylesheets

Avalon uses [Twitter Bootstrap](#) and the [SASS precompiler](#) to build dynamic stylesheets. Along with default [Hydra](#) and [Blacklight](#) styles there are customized overrides. Local stylesheets can be found in `app/assets/stylesheets`.

Edit the [branding.css.scss](#) to customize the presentation or override default styles per your needs. Styles in `branding.css.scss` set variables that are used in other stylesheets to override default Bootstrap and Blacklight styles. All stylesheets are imported into `application.scss`, which prefers `branding.css.scss` over the others.
